9 Change Request Management

Change management requests will help in ensuring the evaluation and approval of modifications to AI powered chatbot in the provided scenario. If there is any change in the Chatbot features, schedule, project scope, security controls, and budget, there should be formal documentation. The agile project software could be used in this context for effective documentation (Reiff and Schlegel, 2022). [1] The responsibility of the project manager rests on recording the requests, evaluation of the impact on resources, risks and quality, dependencies and gaining approval from relevant project stakeholders. After that, the project baseline would be updated. There will not be implementation of any unapproved changes. This process will be helpful for preventing scope creep and also support the completion of the project within a span of 12 weeks.

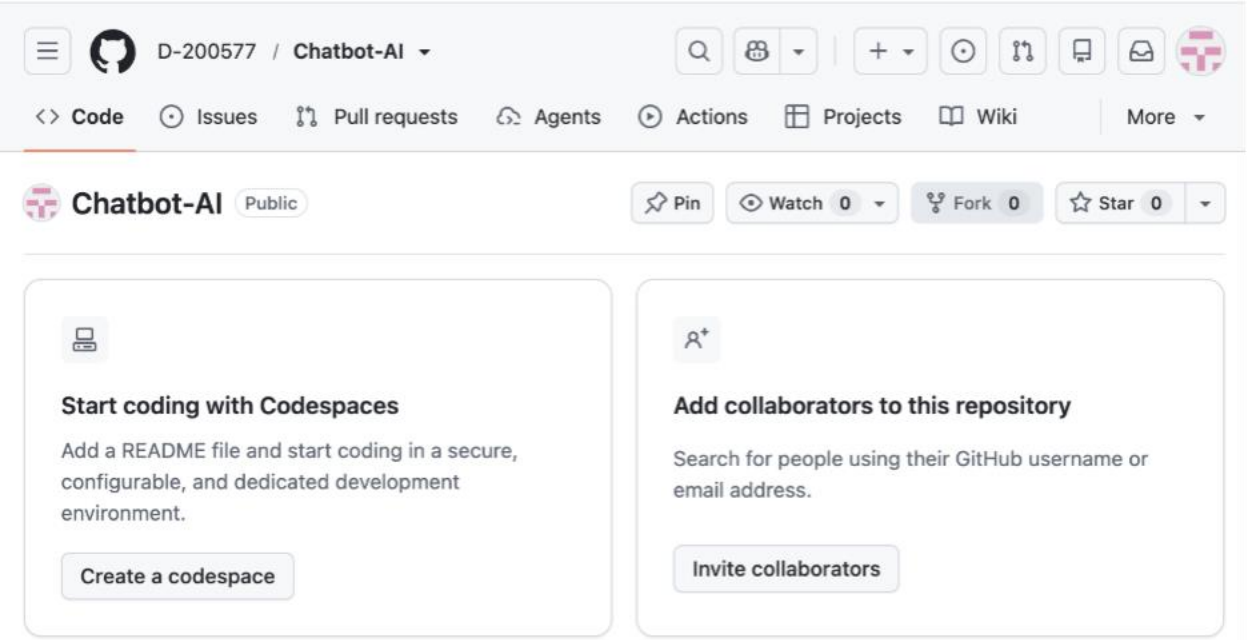

Five stages would be included in the change management process including submission approval, impact, evaluation, implementation and verification. In addition to a new chat feature for automatic refund processing, there would be a requirement of technical complexity evaluation along with customer data, security and testing requirements. Recording of changes is important in project for implementing proactive steps prior to escalation of the issues (Volokh and Hryvkivska, 2025) [2]. The recording of the approved changes will be done through Gantt chart; WBS and risk register for effective update in alignment with the changes.

10 GitHub and Jira Coordination

GitHub and Jira provide support and assistance to task tracking, version control and team coordination (Hakami and Hakami, 2022) [3]. GitHub will play an assisting role in project documentation. It would also document and report information related to approved FAQ samples, Chatbot configuration, files and development artefacts. The approved versions will be included in the main branch and pull requests and features would be included in the supporting branches. Real customer records, passwords, API keys and sensitive information must not be stored in the GitHub repository. Synthetic data should be used for testing, while credentials must be managed securely.

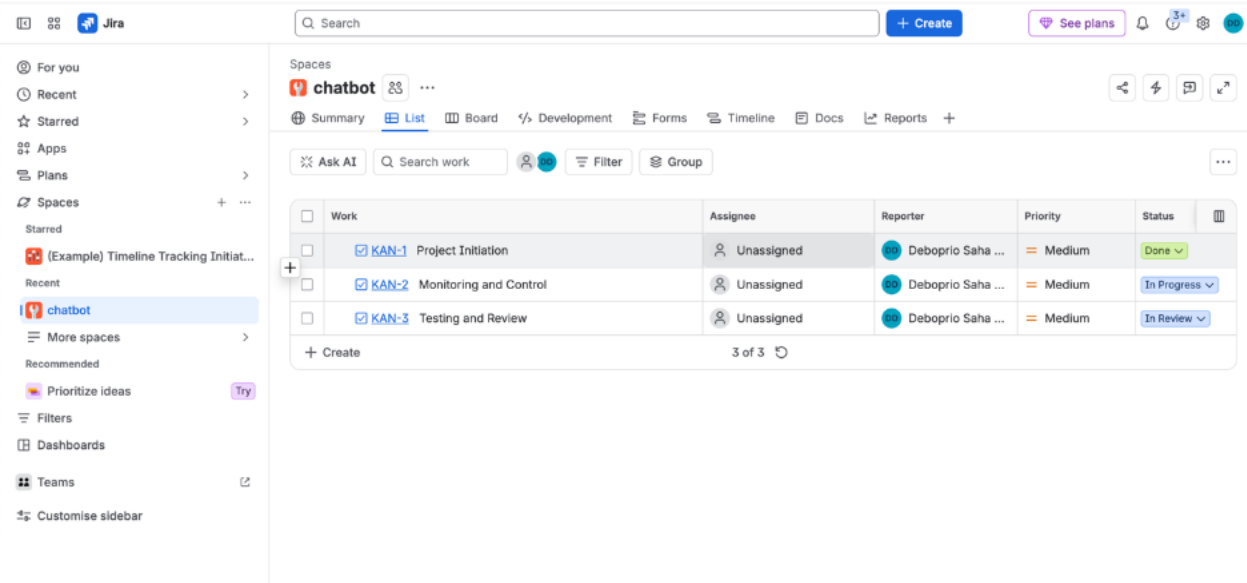

The Github project repository for our project has been created and its available in the below link:

https://github.com/D-200577/Chatbot-AI

The role of Jira lies in project monitoring, task allocation, sprint planning and issue reporting. Jira also helps in deleting or cloning activities in projects (AlHarbi *et al.* 2023) [4]. This would help in time management, prioritisation and acceptance criteria. The request and commitments of GitHub would be linked to relevant issues identified through Jira for maintenance of traceability between proposed changes, testing and development work. The use of these tools will bring improvement in accountability along with monitoring progress in alignment with the agreed schedule.

The Jira project project management kanban has been created where we have started creating the boards and spaces for this project as shown below:

11 Communication Management Plan

Stakeholder	Communication method	Frequency
Project team	Meetings and communication through the use of group messages	Weekly
Project manager	Jira progress and defect tracking	Weekly
Business sponsor	Project progress and milestones review	Fortnightly
Customer support representatives	Requirement gathering and review meetings	At key milestones
Testing and security team	Testing reports and defect tracking	During testing

Table 1: Change Management Plan

Table 1 defines the communication between cultures, including schedule changes, decisions and significant risks faced by relevant stakeholders. It is important to escalate security of privacy concerns to the project manager along with technical experts. Action items, decisions and meetings will also be documented for ensuring accessibility. There would also be use of customer enquiries by the team for development and testing. The review of privacy controls is important against applicable, Australian privacy principles, especially related to the security of personal information.
